Dissertation Title Hydrothermal Synthesis, Characterizations, and Applications of Nanosheets from Thai Natural Magnetic Leucoxene Mineral
Name-Surname Mr. Wissanu Chareerntanom
Program Energy and Materials Engineering
Dissertation Advisor Assistant Professor Sorapong Pavasupree, Ph.D.
Academic Year 2016

ABSTRACT

Titanium dioxide (TiO_2) and the TiO_2 -based materials have been deployed in a wide variety of applications, e.g. in dye-sensitized solar cells, water purification and treatment, photocatalytic water splitting, and gas sensors. Moreover, nanosheets are of special interest because of its transformability into various two-dimensional (2D) functional nanostructures. It has large surface area with high chemical activity and quantum confinement effect. The purposes of this research are a) to investigate the prepared nanosheets from Thai magnetic leucoxene mineral using hydrothermal method, b) to study of the nanosheets properties such as size, shape and crystal structure, and c) to know the application of nanosheets on photocatalytic activity and electromagnetic wave absorber application.

This research has experimentally synthesized the nanosheets from the natural magnetic leucoxene mineral under the hydrothermal synthesis condition of 105°C for 24 hours. Magnetic leucoxene was utilized as the starting material due to its high TiO_2 content (70-80%) and inexpensiveness. The characterization of the synthesized nanosheets was subsequently carried out as follows: crystalline structure, chemical composition, shape, size and specific surface area using X-ray diffraction (XRD), X-ray fluorescence (XRF), scanning electron microscopy (SEM), transmission electron microscopy (TEM) and Brunauer-Emmett-Teller (BET) specific surface area analysis. The said characterization was used to determine the applications of nanosheets on photocatalytic activity and electromagnetic wave absorber applications.

The results indicated that at the beginning, the magnetic leucoxene was of rutile phase while the synthesized nanosheets were of titanate structure ($\text{H}_2\text{Ti}_x\text{O}_{2x+1}$).

After the calcination at the temperature range of 300 and 400 °C, the calcined samples demonstrated TiO₂ (B). At 500 and 600 °C, the calcined nanosheets revealed a bi-crystalline mixture consisting of TiO₂ (B) and anatase TiO₂. At 700–1000 °C, the crystalline structure showed anatase and rutile phase. At 1100 °C, the prepared samples consisted of a mixture of anatase, rutile phase of TiO₂, and Fe₂O₃ phase. The synthesized product also exhibited the flower-like morphology with 2-5 μm in diameter, and the nanosheets structure was slightly curved, with 100nm–2 μm in width and 1-3nm in thickness. At 100–200 °C, the product showed sheets-like structure. At 300–1100 °C, the calcined nanosheets became unstable and began to decompose and transform into nanoparticles. The increasing size of nanoparticle decreased the specific surface area of the nanosheets caused by increasing calcination temperature. Furthermore, the BET specific surface area of the nanosheets was approximately 279.8 m²/g. More importantly, the synthesized nanosheets achieved the higher photocatalytic activity under UV and visible light than the commercial TiO₂ nanoparticles (JRC-01, JRC-03, ST-01 and P-25). The electromagnetic wave absorber coin with nanosheets and the commercial TiO₂ nanoparticles (P-25) can absorb electromagnetic wave in gamma (γ) ray and x-ray region were 96.57 and 89.88 % of the initial intensity, respectively. The electromagnetic wave absorber plates made from the as-synthesized nanosheets and recycled high density polyethylene (HDPE) composite could be used for the electromagnetic wave absorption activities in gamma (γ) ray and x-ray region. This synthesis method provided a simple route to prepared nanostructure materials from low-cost Thai mineral with high potential for energy and environment applications.

Keywords: nanosheets, magnetic leucosene mineral, hydrothermal, titanate, TiO₂

Acknowledgements

For this thesis, first of all, I would like to express my sincere gratitude to my thesis advisor Assistant Professor Dr. Sorapong Pavasupree for the valuable of guidance and encouragement which helped me in all time of my research.

Secondly, I would like to thank to the thesis committees, Assistant Professor Dr. Sommai Pivsa-Art, Associate Professor Dr. Apirat Laobuthee, Associate Professor Dr. Boonyang Plangklang and Dr. Narongchai O-Charoen for their valuable comments and helpful suggestions.

Thirdly, I would like to thank to the RMUTT annual government statement of expenditure in 2016, National Science and Technology Development Agency (NSTDA), National Research Council of Thailand (NRCT) in 2017 and Sakorn Mineral Co., Ltd. for supported in this research.

Finally, I would like to thank to my father and my mother for all love and encouragement.

Wissanu Charerntanom

CHAPTER 1

INTRODUCTION

1.1 Research background

Nanotechnology and nanoscience are the rapid evolution of the novel advance technological materials for the section of energy and environmental. Nanomaterials are study about phenomena and materials at scales between 1 nm to 100 nm. In the recent researches nanotechnologies and nanomaterials are attract tremendous attention. The novel technologies preparation and superior physical properties are development materials to application fields. The most nanomaterials application fields are the fields of energy production and environmental such as fuel cells, thermoelectricity, hydrogen conversion, photovoltaic, and environmental purification [1-11].

TiO₂-related materials and titanate (H₂Ti₃O₇ Na₂Ti₃O₇ Na_xH_{2-x}Ti₃O₇) are importance for environmental purification, industries, and utilizing solar energy. The various applications use TiO₂ for catalysts, water treatment materials, gas sensors and a semiconductor in dye-sensitized solar cell. The nanostructured materials (nanosheets, nanotubes, nanofibers, nanowires and nanorods) have been received considerably attended due to novel applications and their unique properties. Several methods are employ in the preparation of the TiO₂-derive nanomaterials such as carbon nanotube inner templating, anodic oxidation of a titanium sheet, supramolecular assembly templating, electrodeposition, hydrogen treatment, electrospinning, hydrothermal, anodic porous alumina templating, supramolecular assembly templating, and sol-gel [12-41].

Kasuga et al. first proposed synthesis of TiO₂ nanotubes by hydrothermal method. The hydrothermal method is applies prepare low-dimensional TiO₂ nanostructures, such as nanosheets, nanotubes, nanowires, nanoparticles and nanofibers. Hydrothermal is a simple process. Temperatures use in the preparation of an extremely in a closed system, low-cost, environmentally friendly and samples are prepare with a special shape high specific surface area [12, 26-27, 32].

Of particular interest for this experimental research is the hydrothermal method due to its straightforwardness whereby the nanomaterials are synthesized in a closed system [50-51]. Moreover, the synthesized materials would be of a distinctive shape and large specific surface area. In this research, the starting material is the naturally-mineral magnetic leucosene due to its high TiO₂ content (70-80%) and inexpensiveness (USD 0.5/kg). Unlike the authors' previous works in which titanium butoxide was the starting material in the nanosheets synthesis [12] and ilmenite in the synthesis of nanofibers [17] using the hydrothermal technology, this current research

has synthesized the high-photocatalytic nanosheets and electromagnetic wave absorber from the naturally-mineral magnetic leucoxene under the hydrothermal condition.

1.2 Purpose of the Study

- 1.2.1 To prepared nanosheets from Thai magnetic leucoxene mineral by hydrothermal method.
- 1.2.2 To study the properties nanosheets such as size, shape, crystal structure, and so on.
- 1.2.3 To study photocatalytic application of nanosheets.
- 1.2.4 To study electromagnetic wave absorber application of nanosheets.

1.3 Scope of the Study

- 1.3.1 Prepare nanosheets from Thai magnetic leucoxene mineral by simple hydrothermal method.
- 1.3.2 Characterize the properties of nanosheets such as chemical properties of nanosheets by X- ray fluorescence, (XRF), crystal structure with X- ray diffraction, (XRD), shapes and sizes with a scanning electron microscope, (SEM) and transmission electron microscope, (TEM), specific surface area with Brunauer-Emmett-Teller (BET) analysis.
- 1.3.3 Photocatalytic activity will be investigate under UV light and visible light.
- 1.3.4 Electromagnetic wave absorber application will be investigate under grammar ray (γ - ray) and X- ray wavelength.

1.4 Benefits of the Research

- 1.4.1 To obtain nanosheets from raw material of Thailand.
- 1.4.2 To obtain the knowledge about the nanosheets material with unique properties.
- 1.4.3 To obtain the applications of nanosheets such as photocatalytic and electromagnetic wave applications.

CHAPTER 2

BACKGROUNDS AND THORETICAL

2.1 Titanium Dioxide

Titanium dioxide (TiO_2) is known titania or titanium (IV) oxide from a natural occur oxide of titanium element. Titanium dioxide chemical formula is TiO_2 present white powder [35]. TiO_2 is transition metal oxides. TiO_2 found four common polymorphs: (Table 2.1) rutile (tetragonal structure lattice constants $a = 4.5936 \text{ \AA}$, $c = 2.9587 \text{ \AA}$ unit cell contains 6 atoms), anatase (tetragonal structure lattice constants $a = 3.784 \text{ \AA}$, $c = 9.515 \text{ \AA}$) (Figure 2.1), TiO_2 (B) (monoclinic) and brookite (orthorhombic lattice constants $a = 9.184 \text{ \AA}$, $b = 5.447 \text{ \AA}$, $c = 5.154 \text{ \AA}$) (Figure 2.2) [36,]. In high pressures and high temperatures brookite phase and anatase phase transform to the rutile phase more stable than anatase phase for sizes particle greater than 14 nm and grow faster than anatase phase. Rutile phase can stable at up to 60 k bar and photocatalyst activity very poor [37-38]. Oxygen deficiency Titanium dioxide is an n-type semiconductor [39]. The anatase band gap is 3.2 eV, brookite is ~3.2 eV and rutile is 3.0 eV [40]. The investigate photocatalyst is TiO_2 due to low cost, high photo-activity, thermal stability good chemical and low toxicity [41]. Fujishima and Honda reported in 1972 is the first major advance the photoelectrochemical splitting of water The first major advance was in 1972 when Fujishima and Honda reported the photoelectrochemical splitting of water used anode TiO_2 and counter electrode Pt [42].

Table 2.1 Crystal structure data for TiO_2 [43]

Properties	Rutile	Anatase	Brookite

Figure 2.1 Crystal structures of the rutile and anatase phases of TiO_2 [43].

Figure 2.2 Lattice structure of brookite TiO_2 [43].

Table 2.2 Physical properties of TiO_2 [44].

Physical properties of TiO_2	
Molecular weight	79.87g/mol
Density	4.23 g/cm ³
Melting point	1870 °C
Boiling point	2972°C
porosity	0%
Dielectric constant (1 MHz)	85
Thermal conductivity (25°C)	11.7 Wmk ⁻¹
Electrical resistivity (25°C)	10 ¹² ohm.cm
Electrical resistivity (700°C)	2.5x10 ⁴ ohm.cm
Young 's modulus	230 GPa

Table 2.2. shows the TiO_2 physical properties. The TiO_2 energy band gap is 3.2 eV, high photoreactivity, biocompatibility, chemical stability, include strong ultraviolet absorptivity, long-term photostability, non-toxicity and cost-effectiveness due to these properties extraordinary. The utilized several applications of TiO_2 is for energy-related devices, dye-sensitized solar cells (DSSCs), antibacterial compositions, hydrogen storage, self-cleaning ceramics and glass, lithium ion battery, optoelectronic device, photocatalyst humidity sensor, water-splitting, and photocatalyst for organic pollutants degradation [45]. The titanium metal processes and production of TiO_2 pigment shown in Figure 2.3. The chloride process to manufacture titanium pigment to the pigment industry. [46]. Therefore, TiO_2 nanomaterials are prepared by many processes such as micelle and inverse micelle,

hydrothermal, chemical vapor deposition electro-deposition, solvothermal, sol-gel and so on [12-34].

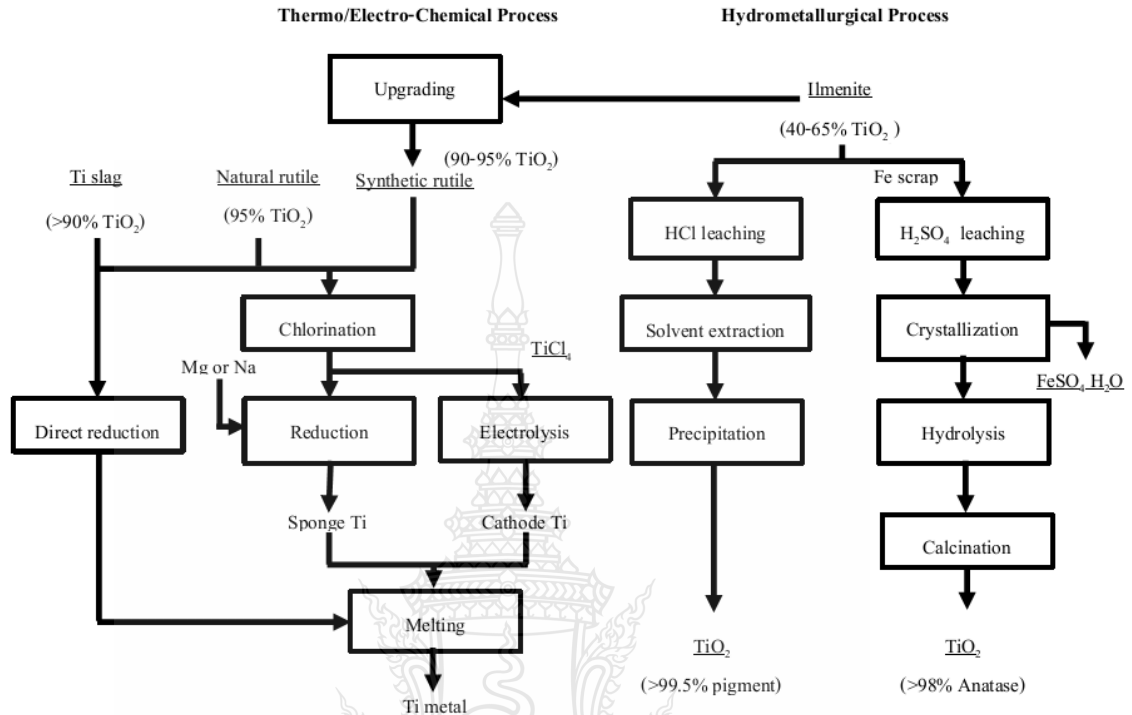

Figure 2.3 The processes production of Ti metal and pigment TiO_2 [46].

2.2 Magnetic Leucoxene Mineral

Magnetic leucoxene mineral is one of TiO_2 -related mineral. The main component TiO_2 mineral has five type minerals such as Ilmenite mineral TiO_2 ~50 - 60 %, Hydro Ilmenite mineral TiO_2 ~60 - 70 %, Magnetic Leucoxene mineral TiO_2 ~70 - 80 %, Leucoxene mineral TiO_2 ~80 - 90 %, Rutile mineral TiO_2 ~90 - 100 %. Magnetic Leucoxene mineral consists mainly of TiO_2 and mixture of portions of the impurities Fe_2O_3 , Al_2O_3 , CaO , SiO_2 , MnO , Nb_2O_5 , MgO and SO_3 .

2.3 Hydrothermal Technology

Sir Roderick Murchison (British Geologist) was the first person to use word “hydrothermal” (1792–1871) to explain action of water at high pressure and high temperature in the earth’s crust to formation of minerals and various rocks. The Hydrothermal method has been gathering interest, and popular from technologists and scientists of properties extraordinary. The word “hydrothermal” has geological origin.

A self-explanatory word “hydro” meaning water and “thermal” meaning heat. [47]. In 1845K. F. E. Schafthaul was the first person to hydrothermal research publication reports the synthesis of freshly precipitated silicic acid in Papin’s digester transformation to tiny quartz crystals. The term hydrothermal usually refers to mineralizers under high pressure and temperature conditions or any heterogeneous reaction in the presence of aqueous solvents [48].

The nanomaterials in hydrothermal processing can be explained to process of preparation nanoparticles from sub-micron by superheated aqueous solution. Nanostructured materials exhibit interesting properties including and unique, improvement of mechanical, electrical, physical and chemical properties [49]. The special advantages of hydrothermal technique is avoidance of pollution, fast reaction times, lowest residence time, lower energy consumption, controlled stoichiometry, lower temperature operations in the presence of the solvent, higher dispersion, narrow particle size distribution, higher rates of reaction, high quality, simple equipment, uniformity, controlled microstructure, excellent reproducibility, high crystallinity, dense particles, controlled morphology, the high control diffusivity in a strong solvent media in a close system, high purity, less defects, and so on [50-53].

The synthesis of hydrothermal offers more advantages than non conventional and conventional synthesis methods. The advanced methods have the respective costs for instrumentation, prepare a large variety of forms, precursors and energy are less for hydrothermal processes. Hydrothermal methods are more environmentally from the environmental perspective than many other methods. The encounter problems of high temperature processes were stress-induced defects and poor stoichiometric control due to volatilization of components such as cooled to room temperature of phase transformations that as the phosphor. Moreover, the phosphor powders ability to precipitate directly from solution the uniformity and regulates rate of nucleation, aging and growth, which aggregation control, affects size, particle sizes and morphology possible with hydrothermal processing that is not possible with many synthesis processes. This beneficial of method to industries which pigments, medical diagnostics pharmaceuticals, materials, will benefit from powders with controlled morphology and size for a wide range of reasons. The preparation difficult to prepare different phases of PbWO_4 phosphor with other synthetic methods allows to the unique pressure-temperature interaction of the hydrothermal method. [52]

Hydrothermal synthesis can be hybridized with other method such as optical radiation, mechano-chemistry, ultrasound, electrochemistry, microwave and hot-pressing to gain advantages such as increase ability to make new materials and enhancement of reaction kinetics. The hybridize method does not need any template, seed, expensive surfactant, and harmful or catalyst thus it is promising for low-cost production and large-scale with high-quality crystals.

2.4 Photocatalysis

Photocatalysis is composed of two words: the first word “photo” from light and the second word “catalysis” from decompose, break apart. The definition of photocatalysis describes in terms of a process where a substance is activated by light, and the rate of a chemical reaction is modified by the photocatalyst, which undergoes a chemical transformation without being involved itself. The difference between a photocatalyst and a conventional thermal catalyst is that the photocatalyst is activated by photons and the thermal catalyst is activated by heat. The reactions of photocatalysis may occur heterogeneously or homogeneously. Heterogeneous photocatalysis is a potential use for energy-related applications and a variety of environmental more than organic syntheses. The photocatalysis of a heterogeneous reaction scheme is the formation of an interface between a product of the reaction and a fluid containing the reactants and a solid photocatalyst [53].

2.5 Semiconductors

The characteristics of electronic materials described by the band theory are semiconductors, insulators, and conductors. Solid material has a large number of atoms that interact, so the energy levels are closely spaced to form bands. Electrons fill these bands from the lowest energy to the highest, and each band has a different energy, similar to a single atom where electrons occupy orbitals. The valence band (VB) is the highest energy filled band, the highest occupied molecular orbital (HOMO) in a molecule. The conduction band (CB) is the next higher band to the lowest unoccupied molecular orbital (LUMO) in a molecule, and is called the energy bandgap (E_{bg}) between the VB and the CB. The insulator, semiconductor, or conductor material is determined by the size of the bandgap [45] (see Figure 2.4).

Figure 2.4 Energy bands in solids: (a) insulator ; (b) semiconductor ; (c) conductor[53].

Electrons are the majority carriers and the electron concentration is called n-type semiconductor, holes are the majority carriers and their concentration is called p-type semiconductors is shown in Figure 2.5.

Figure 2.5 Position of fermi level relative to VB and CB for (a) intrinsic, (b) *n-type* and (c) *p-type* semiconductors [53].

2.6 Electromagnetic Waves

The electromagnetic waves are the waves from component of undulating magnetic fields and electrical fields. The electromagnetic waves have many different kinds such as radio wave, microwave, Infrared, visible light, ultraviolet, X-rays, gamma rays, cosmic rays.

The electromagnetic waves absorbers are material for absorbing electromagnetic waves, magnetic permeability and electric permittivity. The electromagnetic waves absorbers used for absorbing, screen and shield electromagnetic waves to damage of equipment and human. The mechanism of electromagnetic waves absorption starts with first, incident waves come to electromagnetic waves absorbers some waves reflected, some waves transmitted, some secondary reflected and some secondary transmitted are shown in Figure 2.6

Figure 2.6 Mechanism of electromagnetic waves absorption [54].

2.7 X-ray Diffraction Spectroscopy (XRD)

The X-ray Diffraction (Figure 2.7) used to analyze unit cell dimensions, lattice of crystalline substances, details of site-ordering, bond-angles and including bond-lengths. These techniques is non-destructive technique detailed , and observing the scattered intensity of an X-ray beam attack a sample as a function of incident polarization, scattered angle, and energy or wavelength [55-56].

The X-ray diffraction spectroscopy have main three parts sample holder, X-ray detector and X-ray tube. The cathode filament generated X-rays to produce electrons, applying a voltage accelerate electrons to a target and impact target material. When electrons have sufficient energy to dislodge inner shell electrons of the target material, produce characteristic X-ray spectra. These spectra consist of several components, the most common being K_{α} and K_{β} . K_{α} consists, in part, of $K_{\alpha 1}$ and $K_{\alpha 2}$. $K_{\alpha 1}$ has a slightly shorter wavelength and twice the intensity as $K_{\alpha 2}$. The specific wavelengths are characteristic of the target material. Filtering, by foils or crystal monochrometers, is required to produce monochromatic X-rays needed for diffraction. $K_{\alpha 1}$ and $K_{\alpha 2}$ are sufficiently close in wavelength such that a weighted average of the two is used. Molybdenum is the most common target material for single-crystal diffraction, with MoK_{α} radiation = 0.7107\AA . These X-rays are collimated and directed onto the sample. When the geometry of the incident X-rays impinging the sample satisfies the Bragg Equation (equation 2.12), constructive interference occurs. A detector records and processes this X-ray signal and converts the signal to a count rate which is then output to a device such as a printer or computer monitor.

$$n\lambda = 2d \sin\theta \quad (2.12)$$

where n is an integer,

λ is the wavelength of incident wave,

d is the spacing between the planes in the atomic lattice and

θ is the angle between the incident ray and the scattering planes.

The wavelength of electromagnetic radiation explain by this law relates of the lattice spacing and diffraction angle in the crystalline sample. The change geometry of the incident rays, all possible diffraction directions of the lattice, the orientation of the centered crystal and the detector, should be attained detected processed, counted and diffracted X-rays.

Figure 2.8 Basic components of X-ray fluorescence spectrometry [58].

Figure 2.9 The generation of X-ray fluorescence radiation [59].

2.9 Scanning Electron Microscopy (SEM)

The scanning electron microscope (SEM) (Figure 2.10) is an instrument that produces a largely magnified image by using electrons instead of light to form an image. The principle scanning electron microscope start with the electron source generate electrons enter to the system. The electrons were accelerated by the electric field. Then the electrons fill through the condenser lens to make the electron beam and can be adapted to the size of the electron beam. The electron beam is scattering electrons of the sample. It will be the focus of the objective lens. Next, expanded and fit length of electron beams to display for projector lens create signal to translate picture. These signals include secondary electrons that produce SEM images. The SEM techniques magnification f can be magnified range approximately from 20 to 300,000 magnified. [60-61].

Figure 2.10 SEM instrument and schematic of the operation [62].

2.10 Transmission Electron Microscopy (TEM)

The transmission electron microscope is an instrument used electrons instead of light to create a magnified image and applied in photography to detail and high magnification. The principle transmission electron microscope start with the electron source generate electrons enter to the system. The electrons were accelerated by the electric field. Then the electrons fill through the condenser lens to make the electron beam and can be adapted to the size of the electron beam. The electron beam is through the flat and very thin sample when electrons pass through the sample and scattering

electrons. It will be the focus of the objective lens. Next, expanded and fit length of electron beams to display for projector lens create signal to translate picture. Figure 2.11. [63-64].

Figure 2.11 TEM instrument and schematic of the operation [65].

2.11 The Brunauer-Emmett-Teller Analysis (BET)

The Brunauer-Emmett-Teller (BET) (Figure 2.12) analysis specific surface area and pore volume. The Brunauer-Emmett-Teller generally have two cells, one containing sample and the other cells is reference cell sample before the test must provide heat to the cells to displace moisture and molecules contaminated of the surface material. Then evacuate cells to displace molecules and other gases. Next, dipping the two cells into the liquid nitrogen container to low temperatures stat. After, fill nitrogen gas into the cell to adsorption, nitrogen gas is adsorbs on the surface of the material. Then release nitrogen gas to desorption, nitrogen gas is desorbs out the surface of the material, The pursue Phenomenon of the relative pressure and volume of nitrogen gas to predict specific surface area and pore volume of sample material.. [66-67].

Figure 2.12 The schematic of the BET instrument [68].

2.12 UV-Vis Spectroscopy

UV/Vis spectrophotometer (Figure 2.13) is an instrument used to measure the amount of light and intensity light to pass through the sample in the region of ultraviolet (UV) and the visible light. The wavelength is related to the amount and type of the material sample. The sample mostly in organic, organic complexes and inorganic substances that can absorb light in this wavelength range. The sample light absorption properties is accelerated irradiate with UV light or white light with optimal energy to excited electrons. The atoms electrons will absorb the light and energy change the status to the high energy floor level. Then compare light that passes through or reflected from the sample with reference by Beer-Lambert law. The absorbance of the sample will vary depending on the number of absorb light molecules. T UV/Vis spectrophotometer can be measure light absorption in the wavelength range 190 to 900 nm. [69-70].

Figure 2.13 Basic components of UV-Vis spectrometer [70].

2.13 Electromagnetic Wave Absorption Measurement

The principle of electromagnetic wave absorption measurements uses Americium -241 for Grammar ray (γ - ray) primary X-ray sources to generate electromagnetic wave. When the electromagnetic wave move attack the sample some waves absorbs, some waves reflects and some waves transmits. The transmits waves go to electromagnetic detector. The electromagnetic detector receive electromagnetic wave and translate signal to analyze data. (Figure 2.14)

Figure 2.14 Electromagnetic wave absorption measurements.

2.14 Literature Review

Pavasupree, S. et al. [12] study of mesoporous nanosheets TiO_2 structure synthesized by hydrothermal method at $130\text{ }^\circ\text{C}$ for 12 h. The morphology of nanosheets are flower-like structure have diameter about 500 nm to $2\text{ }\mu\text{m}$ (Figure 2.15). The TEM images show diameter of nanosheets TiO_2 is about 50-100 nm in width, thickness is several nanometers (Figure 2.16) and crystalline structure is anatase TiO_2 (Figure 2.17). The specific surface area and pore volume about $642\text{ m}^2/\text{g}$ and pore volume about $0.774\text{ cm}^3/\text{g}$. The structure of nanosheets was changed after heat treatment at $300\text{--}500\text{ }^\circ\text{C}$ into nanorods/nanoparticles composite with anatase TiO_2 structure. The nanosheets showed almost nanoparticles with a mixture of anatase and rutile TiO_2 structure from increasing temperature to $600\text{--}700\text{ }^\circ\text{C}$. Nanosheet was about 7.08% with J_{sc} of $16.35\text{ mA}/\text{cm}^2$ P-25 reached 5.82% with J_{sc} of $12.74\text{ mA}/\text{cm}^2$.

Jitputti, J. et al. [13] study of superstructure flower-like titanate synthesized by hydrothermal method. The titanium tetraisopropoxide is starting material and the solution is ethanol and ammonia use temperature at 120 °C for 24 h. After, that washed by distilled water and ethanol. The diameter of flower-like titanate were 250-450 nm (Figure 2.18), the specific surface area were 350.7 m²/g. Heat increasing temperature to treatments at 500 °C, the titanate nanosheets crystalline structure is convert into anatase TiO₂ with moderate deformation of their structures. The heat treated flower-like titanate at 500 °C showed high photocatalytic activity than the commercial grad TiO₂ anatase powder (ST-01) for H₂ evolution from water splitting reaction (Figure 2.19).

Figure 2.18 SEM image of flower-like nanosheets TiO₂ at x 50,000 magnified [13].

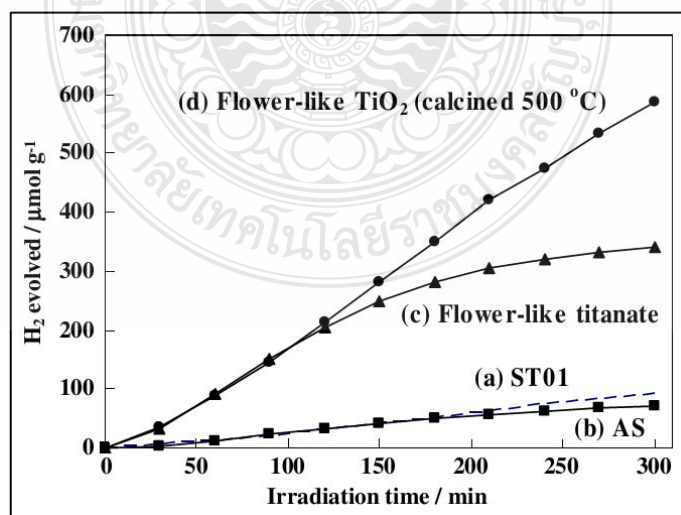

Figure 2.19 Photocatalytic activity for H₂ evolution from water splitting reaction of flower-like nanosheets and commercial nanoparticles TiO₂ [17].

Simpraditpan A. et al. [17] studied on the effect of calcination temperature of nanofibers. The nanofibers are synthesized by hydrothermal method at 130 °C for 72 h. The starting material is natural ilmenite mineral. The nanofibers diameter are 20–90 nm and length are 2–7 μm (Figure 2.20). The as-synthesized nanofibers calcination at 300–400 °C show TiO₂(B), at 500 °C show a mixture of two phases of TiO₂(B) and anatase, at high temperature of 600–1000 °C show a mixture of tri-crystalline of anatase, rutile, and Fe₂O₃ (Figure 2.21). The photocatalytic activity of the nanofibers calcination at 400 °C for 2 h is higher than the commercially TiO₂ nanoparticles powders (P-25, JRC-01, and JRC-03) (Figure 2.22).

Figure 2.20 SEM image of nanofibers at x 10,000 magnified [17].

Pavasupree, S. et al. [71] study of mesoporous anatase TiO_2 nanopowder synthesized by hydrothermal method at $130\text{ }^\circ\text{C}$ for 12 h. The specific surface area BET about $193\text{ m}^2/\text{g}$ and average pore diameter 3-4 nm (Figure 2.23). The anatase TiO_2 showed photocatalytic activity higher than the nanofibers TiO_2 , mesoporous TiO_2 , nanorods TiO_2 , and commercial TiO_2 nanoparticles (P25, JRC-03, and JRC-01) (Figure 2.24). In dye-sensitized solar cells application, the dye-sensitized solar cells efficiency of the cell using P-25 as working electrode was about 5.82%. while the mesoporous anatase TiO_2 showed efficiency about 6.30% (Figure 2.25).

Suzuki et al. [73] study of hydrothermal method to synthesize TiO₂ nanowire structure. The result shows after calcination heat treatment for 4 h air at 300 °C, the synthesized samples were 5-10 % nanowire/nanoparticle. Consisting of fine relatively large particles and nanowires. The composite nanowire/nanoparticle electrode showed higher dye-sensitized solar cells performance than the TiO₂ nanowire structured because high electron transfer a straightforward way is electron expressway concept (Figure 2.29).

Figure 2.29 Electron expressway concept [73].

Fujian et al.[74] study of crystalline mesoporous TiO₂ self-assembly of poly 4-Vinylpyridine template and tetrabutyltitanate precursor-based under high temperature (180°C) hydrothermal conditions. The crystalline structure shows anatase phase of highly crystalline M-TiO₂-ns characters (Figure 2.30). The specific surface area about 120 m²/g, large pore volumes about 0.34 cm³/g and monolithic morphology with crystal sizes around 3–5 μm. The catalytic activities under UV light of M-TiO₂-ns in induced reduction of decabromodiphenyl and oxidation of Rhodamine B higher than those of M-TiO₂ template and nonporous crystalline TiO₂ compare with commercial P25 (Figure 2.31).

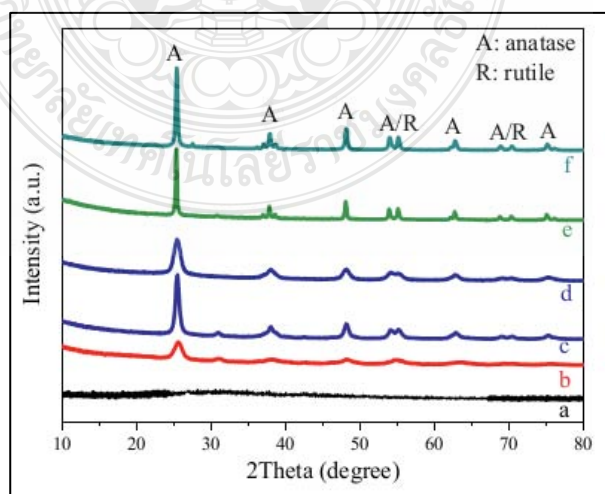

Figure 2.30 XRD patterns of crystalline mesoporous TiO₂ [74].

Lin Wan et al. [77] study of synthesize Fe-doped TiO₂ by hydrothermal method. The resultant photocatalytic activity of ultraviolet, visible light and Phase selection of absorption range of TiO₂ based materials. The ability to control particularly the competition, transformation and the structural evolution, between rutile and anatase phases. The photocatalytic activity of nano crystalline Fe-doped TiO₂ improved

significant visible light photocatalytic activity high than pure TiO_2 nanopowders in degradation effect of methylene blue (Figure 2.37).

Figure 2.37 The photocatalytic activity methylene blue degradation of Fe-doped TiO_2 under visible-light irradiation [77].

Xue Li et al. [78] study of photocatalytic activity synthesize of the nanoparticles TiO_2 , Fe- TiO_2 single-doped and N- TiO_2 Fe- TiO_2 co-doped TiO_2 synthesized by hydrothermal method at 150°C . The resultant crystalline structure for co-doped TiO_2 shows anatase phase. The N- TiO_2 Fe- TiO_2 co-doped TiO_2 specific surface area about $201\text{ m}^2/\text{g}$. The Fe- TiO_2 , N- TiO_2 and P-25 (Degussa) specific surface area are 150, 128 and $55\text{ m}^2/\text{g}$ respectively. The photocatalytic activity of methyl orange degradation co-doped TiO_2 was higher than un-doped TiO_2 and P-25 under visible-light irradiation (Figure 2.38).

Figure 2.38 The photocatalytic activity methyl orange degradation of (a) N -Fe-TiO₂,(b) Fe-TiO₂, (c) N- TiO₂, (d) P-25 (Degussa) and (e) TiO₂ [78].

Swati Sood et al. [79] study of the concentrations of Fe doped nanoparticles TiO₂ in photocatalytic degradation. The results show crystals shape TiO₂ is smaller than dope Fe iron. The TiO₂ are grey particles, the Fe dopant is dark particle (Figure 2.39). The Fe iron dope nanoparticles TiO₂ to photocatalytic degradation for harmful chemical, para nitro phenol and toxic of 0.05 mol % Fe³⁺ can degradation 92% para nitro phenol in 5 h (Figure 2.40).

Figure 2.39 TEM images of Fe iron dope nanoparticles TiO₂ [79].

Figure 2.40 The photocatalytic activity para nitro phenol degradation of Fe iron dope nanoparticles TiO₂ [79].

Panbo Liu et al. [80] study of electromagnetic wave absorption properties of graphene @ Fe₃O₄@PANI decorated with TiO₂ nanosheets. The graphene @ Fe₃O₄@PANI decorated with TiO₂ nanosheets are prepared by hydrothermal method and in situ polymerization. The results show the TiO₂ nanosheets are dispersed randomly and form hierarchical structures on the top of graphene @ Fe₃O₄@PANI (Figure 2.41). Electromagnetic (EM) wave absorption properties of graphene @Fe₃O₄@PANI@ TiO₂nanosheets containing 50wt% paraffin were investigated on the frequency of 2 - 18 GHz. The maximum reflection loss of the nano composites is up to -41.8 dB at 14.4 GHz of a thickness of 1.6 mm, and the absorption bandwidth of R_L < -10 dB is almost up to 3.5 GHz (Figure 2.42).

Figure 2.41 TEM images of GN@Fe₃O₄@PANI@TiO₂ nanosheets [80].

Figure 2.42 Electromagnetic (EM) wave absorption properties of graphene @ Fe_3O_4 @ PANI @ TiO_2 nanosheets[80].

Meng Zong et al. [81] study of microwave absorbing applications in coated Fe_3O_4 composite to graphene oxide (RGO) composite. The TEM images show Fe_3O_4 graphene oxide (RGO) composite, the Fe_3O_4 particle size is 15-25 nm (Figure 2.43). The microwave absorbing applications of RGO/ Fe_3O_4 composite with the thickness of 3.9 mm shows the microwave absorption of -44.6 dB at 6.6 GHz (Figure 2.44).

Figure 2.43 TEM images of Fe_3O_4 graphene oxide (RGO) composite [81].

Figure 2.44 The microwave absorbing applications of RGO/ Fe_3O_4 composite [81].

Kangle, Lv. et al. [82] study of calcination and photocatalytic activity of anatase TiO_2 nanosheets with hydrothermal method used tetra butyl titanate for starting material. The SEM images of the calcination of the sample show morphology is sheet shape and length about 100 nm (Figure 2.45). The photocatalytic activity decrease when increase temperature in calcination because specific surface area decrease when increase temperature in calcination (Figure 2.46).

Figure 2.45 SEM images of (a) T200, (b) T800, (c) T1100, (d) T1250 [82].

Figure 2.46 The photocatalytic activity of anatase TiO_2 nanosheets [82].

Wu J.M. et al. [83] study of dye effluent treatments with hydrothermal method used Ti (IV) ions for starting material. The titania microspheres are aggregate of nanowires diameter about $2 \mu\text{m}$ (Figure 2.47). The specific surface area were $45.4 \text{ m}^2/\text{g}$. The Photo degradation activity of rhodamine B were higher than P25 titania nanoparticles (Figure 2.48).

Figure 2.47 SEM images of titania microspheres[83].

Figure 2.48 The photocatalytic activity rhodamine B degradation of titania microspheres [83].

Huang H. et al [84] study of $\text{TiO}_2\text{-B}$ nanosheets for lithium-ion batteries with hydrothermal method used TiCl_3 aqueous solution for starting material. The resultant the flower-like porous $\text{TiO}_2\text{-B}$ specific surface area were $214.6 \text{ m}^2/\text{g}$. the $\text{TiO}_2\text{-B}$ material exhibits high capacity, good cycling stability and superior rate capability as LIBs anode materials (Figure 2.49).

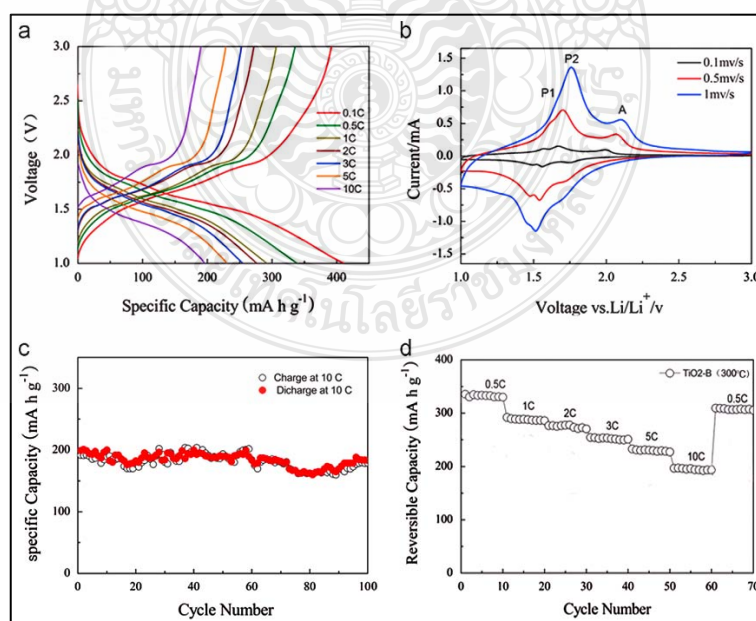

Figure 2.49 The lithium-ion batteries application of $\text{TiO}_2\text{-B}$ nanosheets [84].

Chen K. et al. [85] study of the TiO₂ photocatalytic activity nanosheets to with hydrothermal method used Tetrabutyl titanate (98%) for starting material. The morphological of prepared is nanosheets TiO₂ (Figure 2.50). The photocatalytic degradation of RhB in visible light of TiO₂ nanosheets was higher than P25 nanoparticles (Figure 2.51).

Figure 2.50 SEM images of nanosheets TiO₂ [85].

Figure 2.51 The photocatalytic activity of nanosheets TiO₂ under (a) UV and (b) visible light irradiation [85].

Que Y.-P. et al. [86] study of high crystalline nanosheets. The starting material is titanium isopropoxide TTIP and solution use hydro fluoric acid, polyvinyl pyrrolidone PVP, ethanol for hydrothermal method at 200 °C for 24 h. Next, Cool the sample to room temperature and wash with ethanol. The results show the morphology of the samples is uniform hierarchical flower-like 3D structures. The samples size is 700-800 nm thickness about 13 nm (Figure 2.52). The N₂ adsorption desorption isotherm show hysteresis loop type H3 and isotherms type IV. The specific surface area is 16.67 m²/g and pores volume is 0.167 cm³/g. The hierarchical flower-like 3D structures effect to photoelectric performance to improve electron collection efficiency,

facilitate electron transport and reduce electron recombination for dye-sensitized solar cells.

Figure 2.52 SEM images and TEM images of nanosheets [86].

Shen B. et al. [87] study of graphene oxide film and graphene foam for electromagnetic interference shielding. The graphene oxide film is prepared by evaporation of graphene oxide suspension under mild heating. The graphene foam is prepared by graphene oxide film and use hydrazine-foaming method. The results show the graphene foam has high electromagnetic interference shielding in broadband frequency range of 8.2 - 59.6 GHz than the graphene oxide film. The maximum reflection loss is -26.3 dB at 51 GHz (Figure 2.53). The graphene foam shows performance competitive shielding electromagnetic broadband because porous graphene foams can repeatedly reflect at the cell interfaces due to the impedance between graphene layers and air can enhance transfer micro current energy to heat.

Figure 2.53 The electromagnetic interference shielding of graphene film and graphene foam [87].

Yang Y. et al. [88] study of graphene/Fe₃O₄ hydrogel for electromagnetic wave absorption. The composite hydrogels from Fe₃O₄ nanoparticles and graphene sheets are prepared by hydrothermal method. The nanoparticles Fe₃O₄ size about 13 nm and disperse randomly on the surface of the graphene sheets (Figure 2.54). The results show graphene/Fe₃O₄ hydrogel can remove Rhodamine B is 99.6%. The graphene/Fe₃O₄ hydrogel shows strong and wide in the frequency range 2–20 GHz of electromagnetic wave absorption. The maximum reflection loss is -11 dB at 17.4 GHz. The composite hydrogels show organic pollutant adsorption property and electromagnetic wave absorption because of high adsorption ability and the large surface area of graphene sheets and affect the magnetic properties of Fe₃O₄ materials (Figure 2.55).

Figure 2.54 SEM images and TEM images of graphene/Fe₃O₄ hydrogel [88].

Figure 2.55 The electromagnetic wave absorption of graphene/Fe₃O₄ hydrogel [88].

Yuan, X. et al. [89] study of electromagnetic wave absorption from titanium carbide nanowires. The titanium carbide nanowires are prepared by chloride-assisted carbothermal reaction. The results show morphology and microstructure of titanium carbide nanowires have a diameter about 200–400 nm and lengths up to dozens micrometers (Figure 2.56). The specific surface areas about 186.7 m²/g. The hybrids of titanium carbide nanowires and paraffin show electromagnetic wave absorption activity at 8.2–12.4 GHz in X-band. The sample at thickness of 1.7 mm show the maximum reflection loss is -51.0 dB at 11.8 GHz, and the bandwidth of 3.0 GHz reflection loss of < -10 dB (Figure 2.57).

Figure 2.56 SEM images and TEM images of titanium carbide nanowires [89].

Figure 2.57 The electromagnetic wave absorption of titanium carbide nanowires [89].

Wang, H. et al. [90] study of electromagnetic interference shielding from porous polymeric composites. The porous polymeric composites three-dimensional (3D) networks are prepared by combination of hot-pressing and selective etching with poly(vinylidene fluoride)(PVDF) and multiwall carbon nanotubes (MWCNTs). The results show electrical conductivity of nano composites foam increase when the content of multiwall carbon nanotubes is 15 wt%. The electrical conductivity of pure poly(vinylidene fluoride) is 10^{-16} S/cm and the electrical conductivity of multiwall carbon nanotubes is 15 wt% is 1S/cm. The porous polymeric composites three-dimensional (3D) networks show the electromagnetic interference shielding at the frequency of 8 -12 GHz. The shielding effectiveness is 56.72 dB at thickness about 2 mm and density of 0.79 g/cm^3 (Figure 2.58). The porous polymeric composites three-dimensional (3D) networks are electromagnetic interference shielding because the incident power reflect and scatter many times between multiwall carbon nanotubes and poly(vinylidene fluoride) interfacial areas.

Figure 2.58 The electromagnetic interference shielding of porous polymeric composites [90].

Wang, Y. et al. [91] study of microwave absorption enhancement of $\text{Fe}_3\text{O}_4 @ \text{SnO}_2$ / reduced graphene oxide nanocomposite. The $\text{Fe}_3\text{O}_4 @ \text{SnO}_2$ / reduced graphene oxide nanocomposite are prepared by three-step hydrothermal method. The results show the diameter of Fe_3O_4 nanospheres are about 220 nm. The nanoparticles $\text{Fe}_3\text{O}_4 @ \text{SnO}_2$ core – shell disperse randomly on the surface of reduced graphene oxide (Figure 2.59). The electromagnetic microwave absorption shows $\text{Fe}_3\text{O}_4 @ \text{SnO}_2$ / reduced graphene oxide nanocomposite can absorb microwave in the frequency range of 2 – 18 GHz at room temperature. The microwave absorption shows the maximum reflection loss is – 45.5 dB at 6.4 GHz promising for application in microwave absorbers (Figure 2.60).

Figure 2.59 TEM images of $\text{Fe}_3\text{O}_4 @ \text{SnO}_2$ / reduced graphene oxide nanocomposite [91].

Jia, Q. et al. [93] study of microwave absorption performance from TiO_2 /polyaniline /graphene oxide bouquet-like composites. The TiO_2 /polyaniline /graphene oxide bouquet-like composites are prepared by in-situ oxidation polymerization. The results show morphology of TiO_2 /polyaniline /graphene oxide composites are bouquet-like structures. The microwave absorption performance in the bandwidth absorption in the frequency range of 7.97 -11.88 GHz show the reflection loss is -51.74 dB from TiO_2 /polyaniline /graphene oxide composites at the frequency 9.67 GHz with the thickness of 3.12 mm (Figure 2.62).

Figure 2.62 The microwave absorption performance of TiO_2 /polyaniline /graphene oxide bouquet-like composites [93].

Lu, L. et al. [94] study of electromagnetic wave absorbing application in concrete from TiO_2 . The TiO_2 containing function aggregate electromagnetic wave absorber is preparing by disperse powder TiO_2 into clay and calcined. The results show the TiO_2 containing function aggregate electromagnetic wave absorber has high dielectric constant. The TiO_2 containing function aggregate electromagnetic wave absorber can absorb electromagnetic wave in the frequency range of 8–18 GHz and the maximum reflection loss -10 dB is larger than 8 GHz. The concrete is prepare by function aggregate show higher compressive strength 28 MPa (Figure 2.63). The concrete can use for structural material in the buildings.

3.3 Experimental

3.3.1 Synthesis of TiO₂ nanosheets (Figure 3.11)

In this research, the nanosheets were hydrothermally synthesized using the naturally-mineral magnetic leucosene (Sakorn Minerals, Thailand) as the starting material. In the synthesis process, 16g of the ball-milled (650 rpm for 15 minute) magnetic leucosene mineral was deposited in a Teflon-lined stainless steel autoclave (Figure 1) and then filled with 2000 mL of 5 M NaOH (aq.) prior to heating at 105°C for 24h under continuous stirring. The autoclave was then allowed to cool to room temperature, and the synthesized product was washed multiple times with a 0.1 M HCl (aq.) solution and subsequently with distilled water until the pH value was approximately 7.0. The product was then dried with hot air at 100°C for 12h. Finally, calcination was performed at the temperature range of 100–1,100 °C for 2h and cool to room temperature.

Figure 3.11 Experimental procedure synthesis of TiO_2 nanosheets.

3.4 Characterization

In this research, the characterization of the synthesized nanosheets (i.e. the as-synthesized sample) was carried out: the crystalline structure, chemical composition, shape, size and specific surface area. The crystalline structure and the chemical composition were respectively analyzed by the X-ray diffraction (XRD, PANalytical X'Pert PRO MRD) and X-ray fluorescence (XRF, Oxford, ED-2000) techniques. The shape and size of the as-synthesized sample were determined using a scanning electron microscope (SEM, JEM-6510, JEOL) with acceleration voltages of 5-20kV and a transmission electron microscope (TEM, JEOL JEM-2010 Electron Microscope). The Brunauer-Emmett-Teller technique (BET, Rubotherm, BELSORP-Mini) was used to determine the specific surface area.

3.4.6 Brunauer-Emmett-Teller analysis

Study the specific surface area by Brunauer-Emmett-Teller (BET, Rubotherm, BELSORP - Mini).

Figure 3.17 Brunauer-Emmett-Teller (BET).

3.4.7 Photocatalytic activity determination

The photocatalytic activity was determined using the I_3^- concentration from the photo oxidation reaction of I, which transformed into I_2 in excess of I [5, 27], as per Eqs. (1) and (2).

In the photocatalytic activity analysis, 50mg of the sample and 0.2M potassium iodide solution were filled into a cylindrical vessel. The Photocatalytic activity investigate in equilibrium reaction system after mixing the solution in dark for about 30 min. The vessel was then illuminated with a 15W UV and visible light under

constant stirring at room temperature for 1h. The solution was then separated by the centrifuge method and diluted 10 times prior to the measurement of ion by light absorption at 288nm using a UV-vis spectrometer. In this research, the intensity coefficient was 4.0×10^4 cm mol/l. [96]

3.4.8 Electromagnetic wave absorption measurement

Electromagnetic wave absorption measurements used Americium-241 for gamma ray (γ - ray) and primary X-ray sources. The distance between the gamma ray (γ - ray) and primary X-ray sources and sample, detector were 5, 60 cm respectively.

Figure 3.18 Electromagnetic wave absorption measurements.

CHAPTER 4

RESULTS AND DISCUSSION

4.1 Characterization Results

4.1.1 The physical property and morphology of magnetic leucoxene mineral

The as-synthesized sample is brown, whereas the starting magnetic leucoxene mineral is black. This result indicates that a large portion of Fe impurities are removed by NaOH (aq.) hydrothermal treatment and the neutralization/washing process [31].

Figure 4.1(a) A SEM image of the starting magnetic leucoxene mineral is shown in Fig. 4.1(a), this illustrates the granular structure of the material, with grain size of 150-300 μm while Figure 4.1(b) shows the ball-milled magnetic leucoxene with the reduced grain size of about 0.5-10 μm .

Figure 4.1 The SEM images of: (a) the magnetic leucoxene mineral (b) the ball-milled magnetic leucoxene.

Figure 4.1 (cont.) The SEM images of: (a) the magnetic leucosene mineral (b) the ball-mille magnetic leucosene.

4.1.2 The XRD patterns of the starting magnetic leucosene and the synthesized nanosheets

The XRD patterns of the starting magnetic leucosene mineral and the synthesized sample are shown in Fig. 4.2. The crystalline structure of the starting magnetic leucosene mineral shows the rutile phase, while the crystalline structure of the synthesized nanosheets shows a layer hydrogen titanate $H_2Ti_xO_{2x+1}$ structure, most likely trititanate ($H_2Ti_3O_7$), indicating the existence of hydrogen in the as-synthesized nanosheets [28,31–32,99–102].

Figure 4.2 The XRD patterns of: (a) the magnetic leucoxene mineral, (b) the as-synthesized sample

4.1.4 The chemical composition of the starting magnetic leucoxene and the as-synthesized sample.

The chemical composition during the hydrothermal process, the quantities of impurities, such as Fe₂O₃, Al₂O₃, CaO, SiO₂, MnO, Nb₂O₅ and MgO decrease while the TiO₂ content increase from 79.8 to 83.2 wt%. This may be due to higher solubility of the impurities in the NaOH and HCl aqueous solutions during the preparation process shown in Table 4.1. [103-104].

Table 4.1 Chemical composition of the natural magnetic leucoxene mineral and the as-synthesized nanosheets

Composition	Magnetic leucoxene mineral	As-synthesized nanosheets
TiO ₂	79.8%	83.2%
Fe ₂ O ₃	9.59%	7.73%
CaO	0.981%	0.775%
ZrO ₂	0.838%	0.685%
Nb ₂ O ₅	0.467%	0.399%
SiO ₂	1.95%	0.389%
MgO	0.319%	0.246%
SO ₃	0.213%	0.187%
MnO	0.207%	0.185%
K ₂ O	0.179%	0.135%
Cr ₂ O ₃	1730 PPM	929 PPM
Cl	972 PPM	750 PPM
Al ₂ O ₃	1.95%	0.043%
Ta ₂ O ₅	495 PPM	429 PPM
PbO	517 PPM	380 PPM
ThO ₂	491 PPM	352 PPM
Sc ₂ O ₃	240 PPM	180 PPM
Y ₂ O ₃	213 PPM	121 PPM
SrO	44 PPM	39.7 PPM
Na ₂ O	0%	1.29%

4.1.4 The physical property and morphology of as-synthesized nanosheets from magnetic leucoxene mineral

Figures 4.3(a)-(c) respectively show the SEM images of the as-synthesized sample at 10,000x, 15,000x, and 50,000x magnification for the group of flower-like morphology. The flower-like structure have a diameter about 2 μm to 5 μm . the flower-like morphology compose of nanosheets. To confirm the formation of nanosheets are use TEM analysis, and a representative image show in Figures 4.4 (a)-(d). From the TEM images, it can be observed that the as-synthesize sample showed sheets –like structure. The nanosheets structure is slightly curve and approximately 100 nm to 2 μm in width and several nanometers in thickness. The sheets radiated in all directions to form flower-like morphology, mainly as a result of the hydrothermally synthetic treatment [105].

Figure 4.3 SEM images of the synthesized nanosheets: (a) 10,000x, (b) 15,000x, magnifications (c) 50,000x magnifications.

Figure 4.3 (cont.) SEM images of the synthesized nanosheets: (a) 10,000x, (b) 15,000x, magnifications (c) 50,000x magnifications.

4.1.5 The mechanism transition of as-synthesized nanosheets from magnetic leucoxene mineral

Figures 4.5 illustrates the mechanism transition of as-synthesized nanosheets structures during the hydrothermal process. The hydrothermal reaction progresses, the ball-mille magnetic leucoxene have energy by heat and pressure, and then lamellar nanosheets are exfoliate from the particles of starting materials. Next, the lamellar nanosheets have energy by heat and pressure, and then then lamellar nanosheets are transformation to flower-like structure for more thermal stability [12, 26, 106-107].

Figure 4.5 Scheme of the transition process of the as-synthesized nanosheets structures during the hydrothermal process.

4.1.5 The nitrogen adsorption isotherm of the as-synthesized nanosheets

Figure 4.6 depicts the nitrogen adsorption isotherm of the as-synthesized nanosheets which is of a typical IUPAC type IV pattern, with the sharp inflection of nitrogen adsorption volume at P/P_0 of 0.40 (H2 type hysteresis loop), indicating the existence of mesoporous materials [4-5, 7, 103-104] with the pore size distribution of 3–35nm (the inset). The BET specific surface area and the pore volume of the as-synthesize nanosheets are $279.8 \text{ m}^2/\text{g}$ and $0.513 \text{ cm}^3/\text{g}$, respectively. As a comparison, Figure 4.7 illustrates the nitrogen adsorption isotherm of the commercial TiO_2 nanoparticles (P-25). The isotherm is of an IUPAC type II with a H3 type hysteresis loop typical of macroporous materials [105], similar to that of TiO_2 , and the pore size distribution (the inset) is about 3–65nm. The BET surface area and the pore volume of the P-25 specimen are $46.92 \text{ m}^2/\text{g}$ and $0.306 \text{ cm}^3/\text{g}$, respectively.

Figure 4.6 The nitrogen adsorption isotherm pattern of the as-synthesized nanosheets and the pore size distribution with the pore diameters of 3–35nm (inset)

Figure 4.7 The nitrogen adsorption isotherm pattern of the commercial TiO_2 nanoparticles (P-25) and the pore size distribution with the pore diameters of 3–65nm (inset).

4.1.5 The BET specific surface areas of the starting material and the as-synthesized sample

Determination of the specific surface area of the starting materials and the as-synthesized sample that measure by the BET (Brunauer-Emmett-Teller) using adsorption of nitrogen. The starting materials are the specific surface area of around $0 \text{ m}^2 / \text{g}$. When the as-synthesized sample by hydrothermal process at temperature of $105 \text{ }^\circ\text{C}$ over a period of 24 h, the specimens are prepare with specific surface area and pore volume around. $279.8 \text{ m}^2 / \text{g}$ and $0.513 \text{ cm}^3 / \text{g}$ respectively, the as-synthesized nanofibers from previous works about $49 \text{ m}^2 / \text{g}$ and $0.159 \text{ cm}^3 / \text{g}$ respectively, commercial TiO_2 nanoparticles(P-25) about $46.97 \text{ m}^2 / \text{g}$ and $0.306 \text{ cm}^3 / \text{g}$ respectively. The specific surface area of the as-synthesized nanosheets samples are 270-280 times greater than the starting material and compare with commercial TiO_2 nanoparticles (P-25) were the specific surface area and pore volume are more than the as-synthesized nanofiber from previous works and the commercial TiO_2 nanoparticles(P-25) shown in Table 4.2.

Table 4.2 The BET specific surface areas and pore volumes

Samples	BET specific surface area (m^2/g .)	pore volume (cm^3/g .)
Magnetic leucoxene (starting material)	~ 0	-
Nanofibers (previous work)	49	0.159
Nanosheets (this study)	279.70	0.513
Commercial TiO_2 nanoparticles (P-25)	46.97	0.306

4.1.6 Photocatalytic activity

The Photocatalytic activity was investigate in equilibrium reaction system after mixing the solution in dark for about 30 min [96]. The I_3^- concentration at 60 min of the irradiation period of the as-synthesized nanosheets is about $7.71 \times 10^{-4} \text{ M}$. (Fig. 4.8) which is higher than that of the other synthesized (i.e., the white pigment TiO_2 and the commercial grade TiO_2 nanoparticles (P-25)) which exhibit I_3^- concentration about 0.073×10^{-4} , and $3.29 \times 10^{-4} \text{ M}$, respectively. The introduction of mesopore into titania photocatalyst substantially improve the photocatalytic performance [6]. The flower-like

titanate superstructure show high photocatalytic activity due to their unique structure [8]. The nanosheets have good crystallinity and well-defined chemical composition and exhibit distinctive physicochemical properties. Therefore, these nanosheets become a potential building block for the construction of nano materials in the fields of photocatalysis, photoluminescence, and photo electrochemistry. The integration of noble metal nanosheets at the surface of TiO_2 has been a widely successful strategy and recognize for improving the photocatalytic activity of TiO_2 . The nanosheets of TiO_2 , $\text{TiO}_2/\text{Fe}_3\text{O}_4$ in the composition has been promoting faster interfacial electron transfer cause of improve photocatalytic activity [97,108-110].

Figure 4.8 The photocatalytic activity (I_3^- concentration) of the nanosheets TiO_2 , white pigment TiO_2 , commercial TiO_2 nanoparticles (P-25).

4.2 Effect of Calcination Temperature on Structure and Photocatalytic Activity

4.2.1 The XRD patterns of the as-synthesized samples and the samples calcination for 2 h at 100 – 1,100 °C.

The XRD patterns of the as-synthesized samples and the samples calcination for 2 h at 100 - 400 °C is show in figure 4.9 (a). At 100 and 200 °C, the crystalline structure of the as-synthesized nanosheets show a layer of hydrogen titanate $\text{H}_2\text{Ti}_x\text{O}_{2x+1}$ structure, most likely trititanate ($\text{H}_2\text{Ti}_3\text{O}_7$). At 300 and 400 °C, the calcined samples

show TiO_2 (B). The nanosheets are dehydrate and recrystallize into the phase of TiO_2 (B). Moreover, the intensity peaks show the TiO_2 (B) decrease while the calcination temperatures increase. [28, 31–32, 99–102]

The XRD patterns of the as-synthesized samples calcination at 500–1100 °C for 2 h are show in Figure 4.9 (b). At 500 and 600 °C, the calcination nanosheets show a bi-crystalline mixture consisting of anatase TiO_2 and TiO_2 (B). Recent research studies found a bi-crystalline mixture consisting of anatase TiO_2 and TiO_2 (B) nanostructure.[17] At 700–1000 °C, the as-synthesized samples consist of a mixture of anatase and rutile. The phase of TiO_2 (B) disappears, and the transformation structure to anatase and rutile phase TiO_2 . In this temperature range the rutile phases TiO_2 begin demonstrate. The rutile phase is increases when the calcination temperatures increase. At 1100 °C, The as-synthesized samples are consist a mixture of anatase, rutile phase of TiO_2 , and Fe_2O_3 phase. [28, 31–32, 99–102]

Figure 4.9 The XRD patterns of: (a) the magnetic leucoxene mineral, the calcination is perform at the temperature range of 100–400 °C, (b) the calcination is perform at the temperature range of 500–1,100 °C.

Figure 4.9 (cont.) The XRD patterns of: (a) the magnetic leucoxene mineral, the calcination is performed at the temperature range of 100–400 °C, (b) the calcination is performed at the temperature range of 500–1,100 °C.

4.2.2 The physical property and Morphology of the as-synthesized samples and the samples calcination for 2 h at 100 – 1,100 °C.

To confirm the formation of nanosheets is use TEM analysis. As show in figure 4.10 (a), it can be observe that the as-synthesized sample show sheets-like structure. The nanosheets structure is slightly curve and approximately 100 nm to 2 μm in width and several nanometers in thickness. The sheets radiated in all directions to form flower-like morphology, accomplish mainly by hydrothermal synthesis. The structure may be the results of the orient attachment effect during crystal grow. The method control the self-assembly of nanostructures and obtain TiO₂ spheres, compose of nanosheets hierarchical structures to flower-like TiO₂ nanosheets [104].

Figure 4.10 (b–l) shows the TEM images of the as-synthesized samples and the samples calcination for 2 h at 100 to 1100 °C. At 100 and 200 °C, the morphology of sample show sheets–like structure. At 300–500 °C, the sheets–like morphology become unstable and begin crack inside the sheets. At 600–900 °C, the morphology of sample begins nanoparticles structure. At 1,000–1,100 °C, the nanoparticles morphology is increasing size. At 300–1100 °C, the calcination nanosheets become unstable and began to decompose and transform into nanoparticles and increasing size. The increasing sizes of nanoparticles decrease the specific surface area of the nanosheets cause by increasing calcination temperature. [14-15, 17]

4.2.3 The photocatalytic activity of the as-synthesized samples and the samples calcination for 2 h at 100 – 1,100 °C.

In this experimental research, the photocatalytic activity is determined using the I_3^- concentration. In figure 4.11, the I_3^- concentration of the as-synthesized nanosheets, given the 60-minute UV light irradiation period, is approximately $3.22 \times 10^{-4} M$, which is noticeably higher than those of the commercial micro-size TiO_2 (white pigment) and the commercial grade TiO_2 nanoparticles (JRC-01, JRC-03, ST-01 and P-25), whose I_3^- concentrations are respectively 0.43×10^{-4} , 1.08×10^{-4} , 0.66×10^{-4} , 1.30×10^{-4} and $1.80 \times 10^{-4} M$. The samples calcination for 2 h at 100 – 1,100 °C, I_3^- concentrations are respectively 3.18×10^{-4} , 3.13×10^{-4} , 3.06×10^{-4} , 3.03×10^{-4} , 2.75×10^{-4} , 2.73×10^{-4} , 2.67×10^{-4} , 2.68×10^{-4} , 2.72×10^{-4} , 2.81×10^{-4} and $2.87 \times 10^{-4} M$. While, The I_3^- concentration of the as-synthesized nanosheets, given the 60-minute visible light irradiation period, is approximately $2.21 \times 10^{-4} M$, which is noticeably higher than those of the commercial micro-size TiO_2 (white pigment) and the commercial grade TiO_2 nanoparticles (JRC-01, JRC-03, ST-01 and P-25), whose I_3^- concentrations are respectively 0.06×10^{-4} , 0.29×10^{-4} , 0.10×10^{-4} , 0.46×10^{-4} and $0.49 \times 10^{-4} M$. The samples calcination for 2 h at 100 – 1,100 °C, I_3^- concentrations are respectively 2.11×10^{-4} ,

1.88×10^{-4} , 1.78×10^{-4} , 1.65×10^{-4} , 1.59×10^{-4} , 1.57×10^{-4} , 1.50×10^{-4} , 1.65×10^{-4} , 1.77×10^{-4} , 1.82×10^{-4} and 1.85×10^{-4} M. In addition, the distinctive flower-like structure of the nanosheets contributes to the high photocatalytic activity [13]. The introduction of mesopore into the titanium-base photocatalyst substantially improved the photocatalytic performance [6]. After the samples calcination, the nanosheets structure become unstable and begin to decompose and transform into nanoparticles, that is the cause of specific surface area decrease and lower photocatalytic activity. At 900 – 1,100 °C, more anatase TiO₂ phase is high photocatalytic activity than rutile phase because the energy position of the conduction band edge of anatase is higher than that of rutile [14-15,17, 111]. Furthermore, the high proportion of Fe₂O₃ (9.59%) in the starting material (i.e. the naturally-occurring magnetic leucoxene) extends the photocatalyst's response into the visible region and at the same time improves the oxidation of several organic compounds, e.g. chloroform, toluene, benzene, alcohols and ethers, as opposed to many other starting materials that require the iron-doping [111].

The hydrothermally synthesized nanosheets afford us with the advantages of large specific surface area, confined atomic-level thickness and salient surface-chemical states, in addition to the distinct mechanical, thermal, electronic and optical properties [112]. Furthermore, the 2D nanostructured metal oxides could become a building block for the construction of nano-materials in the fields of photocatalysis [110] and photo-electrochemistry [109].

Figure 4.11 The photocatalytic activity (I_3^- concentration) of the as-synthesized nanosheets, the calcination is performed at the temperature range of 100–1,100 °C, the commercial micro-size TiO₂ (white pigment) and the commercial TiO₂ nanoparticles (JRC-01, JRC-03, ST-01 and P-25).

4.3 Electromagnetic Wave Absorption Activities

4.3.1 The XRD patterns of the electromagnetic wave absorber plates

The XRD patterns of the electromagnetic wave absorber plates are shown in Figure 4.12. The crystalline structure of the electromagnetic wave absorber plates shows the high crystallinity phase of polyethylene. The amount of crystalline phase of polyethylene decreases when the amount of the as-synthesized nanosheets increases. The nanosheets insert between chains of polyethylene affect to more space difficultly chains orientation cause of decrease crystallinity phase of polyethylene.

Figure 4.12 The XRD patterns of the electromagnetic wave absorber plates (a) the magnetic leucoxene mineral and the as-synthesized sample.

4.3.2 The electromagnetic wave absorption activities in gamma (γ) ray and x-ray region of electromagnetic wave absorber coin

The electromagnetic wave absorption activities in gamma (γ) ray and x-ray region of electromagnetic wave absorber coin are shown in Figure 4.13. The electromagnetic wave absorber coin with nanosheets and the commercial TiO₂ nanoparticles (P-25) can absorb electromagnetic wave in gamma (γ) ray and x-ray

region from I0 18696 to 642 and 1892 counts per minute were 96.57 and 89.88% of the initial intensity, respectively. The percentage of electromagnetic wave absorption activities increase while the BET specific surface area increase and the electromagnetic wave absorption activities of electromagnetic wave absorber can be explained by material for electromagnetic wave absorber such as TiO_2 , Fe/TiO_2 and $\text{Fe}_3\text{O}_4/\text{TiO}_2$ for electromagnetic waves absorber can absorb electromagnetic waves. [80-81, 87-95].

Figure 4.13 Electromagnetic wave absorption activities of electromagnetic wave absorber coin between the synthesized nanosheets and the commercial TiO_2 nanoparticles (P-25).

The electromagnetic wave absorption activities in gamma (γ) ray and x-ray region of electromagnetic wave absorber plates at the thickness 0-27 mm are shown in Figure 4.14. The electromagnetic wave absorber plates with 100 % recycled HDPE can absorb electromagnetic wave in gamma (γ) ray and x-ray region from I0 18,696 to 12,653 counts per minute was 32.32 % of the initial intensity. The electromagnetic wave absorber plates with 25, 50, 75 and 100 % nanosheets from magnetic leucosene mineral can absorb electromagnetic wave in gamma (γ) ray and x-ray region from I0 18,696 to 7,567, 5,807, 3844 and 642 counts per minute were 59.53, 68.94, 79.44 and 96.57% of the initial intensity, respectively. The percentage of electromagnetic wave absorption activities increase while the nanosheets contain increase. The electromagnetic wave absorption activities of electromagnetic wave absorber can be explained by material for electromagnetic wave absorber such as TiO_2 , Fe/TiO_2 and

$\text{Fe}_3\text{O}_4/\text{TiO}_2$ for electromagnetic waves absorber can absorb electromagnetic waves. [80-81, 87-95].

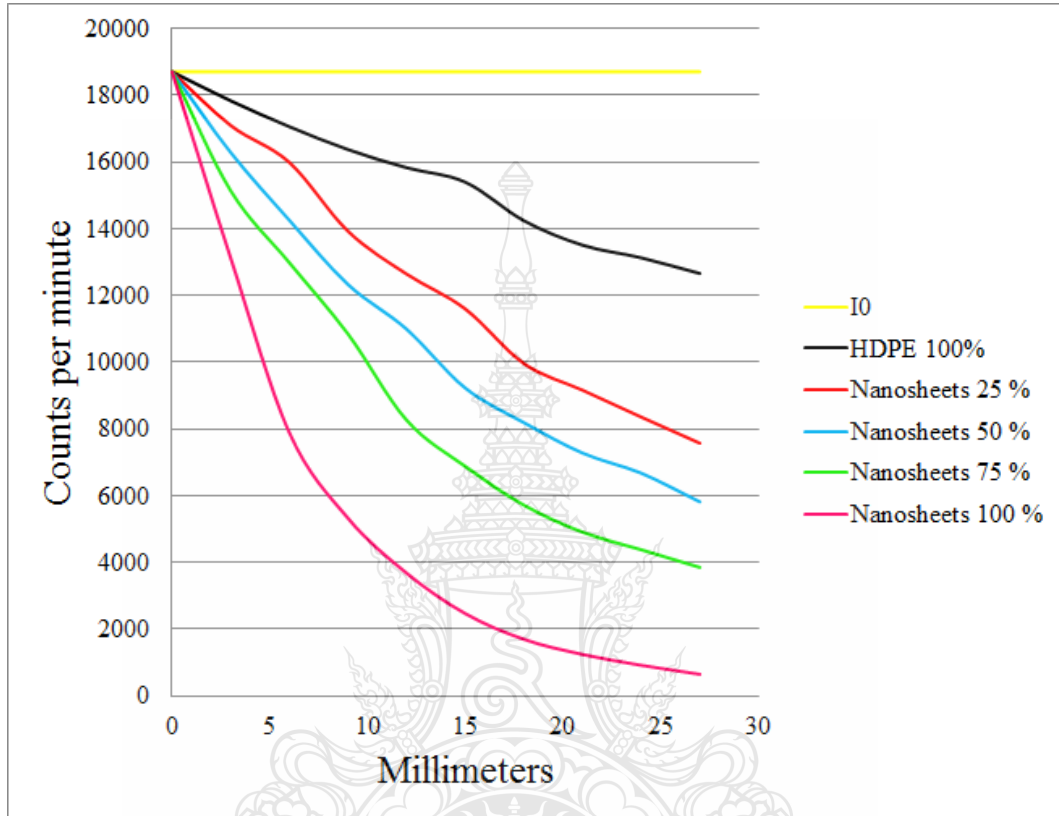

Figure 4.14 Electromagnetic wave absorption activities of electromagnetic wave absorber plates made from different ratios between the recycle HDPE and the synthesized nanosheets.

The scheme of electromagnetic wave absorption activities are shown in Figure 4.15. The initial electromagnetic wave going from Americium 241 primary source for gamma (γ)-ray and x-ray attack the electromagnetic wave absorber. Some initial electromagnetic wave had been reflection. Some initial electromagnetic wave hit particle of minerals has been reflection and multiple reflections to next minerals. Some electromagnetic wave can be absorption in electromagnetic wave absorber. Some electromagnetic wave can be transmitted. The transmission electromagnetic wave can be detected by detector.

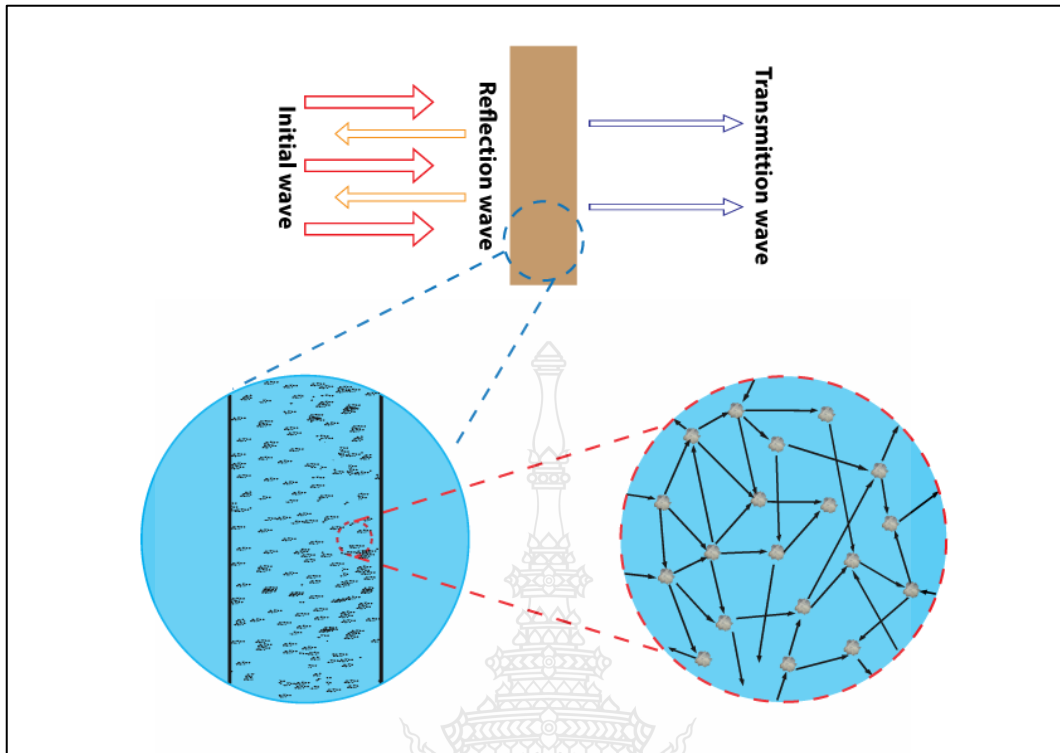

Figure 4.15 Scheme of the electromagnetic wave absorption activities.

CHAPTER 5

CONCLUSIONS AND RECOMMENDATIONS

This experimental research has synthesized the nanosheets from the naturally-mineral magnetic leucoxene under the hydrothermal synthesis condition of 105°C for 24h. The experiment opted for the naturally-mineral magnetic leucoxene as the starting material due to its high TiO₂ content (70-80%) and inexpensiveness (USD 0.5/kg).

The analysis results indicated that the magnetic leucoxene mineral is of rutile phase while the synthesized nanosheets are of titanate structure (H₂Ti_xO_{2x+1}). In addition, the hydrothermal treatment could remove parts of the impurities in the starting material, including Fe₂O₃, Al₂O₃, CaO, SiO₂, MnO, Nb₂O₅, MgO and SO₃, while increasing the TiO₂ content from 79.8 to 83.2wt%. The analysis also revealed that the flower-like structure of the nanosheets was slightly curved, with 100nm–2µm in width and 1-3nm in thickness. Moreover, the BET specific surface area and the pore volume of the synthesized nanosheets were respectively 279.8m²/g and 0.609cm³/g.

After calcination at the temperature range of 300 and 400 °C, the calcined samples demonstrated TiO₂ (B). At 500 and 600 °C, the calcined nanosheets revealed a bi-crystalline mixture consisting of TiO₂ (B) and anatase TiO₂. At 700–1000 °C, the crystalline structure shows anatase and rutile phase. At 1100 °C, the prepared samples consisted of a mixture of anatase, rutile phase of TiO₂, and Fe₂O₃ phase. At 100–200 °C showed sheets-like structure. At 300–1100 °C, the calcined nanosheets became unstable and began to decompose and transform into nanoparticles. The increasing size of nanoparticle decreased the specific surface area of the nanosheets, caused by increasing calcination temperature. More importantly, the experimental nanosheets achieved the higher photocatalytic activity than did the commercial TiO₂ nanoparticles (JRC-01, JRC-03, ST-01 and P-25).

The electromagnetic wave absorber coin with nanosheets and the commercial TiO₂ nanoparticles (P-25) can absorb electromagnetic wave in gamma (γ) ray and x-ray region were 96.57 and 89.88% of the initial intensity, respectively. The electromagnetic wave absorber plates with 100 % recycled HDPE can absorb electromagnetic wave in gamma (γ) ray and x-ray region was 32.32 % of the initial intensity. The electromagnetic wave absorber plates with 25, 50, 75 and 100 % nanosheets from magnetic leucoxene mineral can absorb electromagnetic wave in gamma (γ) ray and x-ray region were 59.53, 68.94, 79.44 and 96.57% of the initial intensity, respectively. The electromagnetic wave absorber plates made from the as-synthesized nanosheets

could be used for the electromagnetic wave absorption activities in gamma (γ) ray and x-ray region.

Recommendations

This research is hydrothermal synthesis, characterizations, and applications of nanosheets from Thai natural magnetic leucosene mineral. The future work includes the development of nanomaterials with unique structures and properties from Thai minerals. For example, the using of the other minerals in Thailand as the starting materials and the increasing of reactor size for pilot plant and commercial products. Evaluate these materials as an electrode in solar cells and optimize the synthesis for this application.

APPENDICES
(List of Publications)

List of Publications

International Journal

1. **Wissanu Charerntanom** Wisanu Pecharapa Suttipan Pavasupree and Sorapong Pavasupree “Effect of calcination temperature on structure and photocatalytic activity under UV and visible light of nanosheets from low-cost magnetic leucoxene mineral” *Photonics and Nanostructures– Fundamentals and Applications* 25(2017) 38–45.
Impact Factor 2016 = 1.705
<https://doi.org/10.1016/j.photonics.2017.04.007>

International Conferences

1. **W. Charerntanom**, A. Simpraditpan, N. O-Charoen, N. Srisawat, W. Pecharapa and S. Pavasupree “Hydrothermal preparation and MB photocatalytic activity under UV light of nanosheets from natural magnetic leucoxene mineral” *Proceeding, Science and Technology of Emerging Materials (STEMa 2016)*, Pattaya, Thailand, July 27-29, 2016, pp. 23-26.
2. **W. Charerntanom**, A. Simpraditpan, N. O-Charoen, N. Srisawat, W. Pecharapa and S. Pavasupree “Preparation of n-type semiconductor nanosheets from natural Thai ilmenite mineral for electromagnetic wave absorber” *Proceeding, Science and Technology of Emerging Materials (STEMa 2016)*, Pattaya, Thailand, July 27-29, 2016, pp. 31-34.
3. **W. Charerntanom**, N. O-Charoen, K. Sungsanit, V. Chobpattana, W. Pecharapa and S. Pavasupree “Preparation and high photocatalyst nanosheets from natural Thai magnetic leucoxene mineral,” *13th Eco-Energy and Materials Science and Engineering Symposium (13th EMSES 2016)*, Udonthani, Thailand, December 1-3, 2016, pp. 280-283.

National Conferences

1. **W. Charerntanom**, J. Numprasert, P. Kummeesith, C. Sea-aung, N. O-Charoen, K. Sungsanit, S. Jaiyen, N. Srisawat and S. Pavasupree “Preparation of electromagnetic wave absorber plate using recycled HDPE and micro materials from Thai minerals” *Proceeding, Industrial*

Engineering Network Conference 2016 (IE NETWORK 2016), Kosa Hotel, Khon Kaen, Thailand, July 7-8, 2016, pp. 1300-1305.

2. **W. Charerntanom**, N. O-Charoen, S. Jaiyen and S. Pavasupree “Preparation of electromagnetic wave absorber plate using recycled HDPE and micro materials from natural Thai rutile minerals” Proceeding, The 2nd National Conference on Industrial Technology and Engineering (NCITE 2016), Ubonratchathani, Thailand, October 19, 2016, pp. 191-197.
3. **W. Charerntanom**, N. O-Charoen and S. Pavasupree “Preparation of electromagnetic wave absorber plate using recycled HDPE and micro materials from natural Thai magnetic leucoxene minerals” Proceedings of the 9th Conference of Electrical Engineering Network of Rajamangala University of Technology 2017 (EENET 2017) KP Grand Hotel Chanthaburi, Thailand, May 2-4, 2017, pp. 618-621.

Petty Patent

1. Petty Patent “The preparation of nanomaterial from magnetic leucoxene mineral for X-ray absorption and shielding” Inventor / designer **Mr. Wissanu Charerntanom** and Assistant Professor Dr. Sorapong Pavasupree Patent number. 11668 Request number. 1503002104 (December 14 2015).
2. Petty Patent “The preparation of nanosheets from ilmenite mineral for textile dye degradation” Inventor / designer **Mr. Wissanu Charerntanom** and Assistant Professor Dr. Sorapong Pavasupree Patent number. 11669 Request number. 1503002105 (December 14 2015).
3. Petty Patent “The preparation of nanosheets from magnetic leucoxene mineral for photocatalyst” Inventor / designer **Mr. Wissanu Charerntanom** and Assistant Professor Dr. Sorapong Pavasupree Patent number. 11670 Request number. 1503002106 (December 14 2015).

Awards

1. Best paper presentation award

W. Charerntanom, N. O-Charoen, S. Jaiyen and S. Pavasupree “Preparation of electromagnetic wave absorber plate using recycled HDPE and micro materials from natural Thai rutile minerals” Proceeding, The 2nd National Conference on Industrial Technology and Engineering (NCITE 2016), Ubonratchathani, Thailand, October 19, 2016.

2. Best engineering invention contest

W. Charerntanom and S. Pavasupree “Preparation of nanosheets from magnetic leucoxene mineral for photocatalytic activities and electromagnetic wave absorber application” The 6th RMUTT Young Talent Inventor Awards, Rajamangala University of Technology Thanyaburi, June 6, 2017.

Biography

Name - Surname Wissanu Charerntanom

Date of Birth 12 September 1983

Address 110/15 Moo 1, Tambon Nong Sang district
Wapipathum Mahasarakham 44120

Education Bachelor's Degree in Petrochemicals and Polymeric
Material Engineering, Faculty of Engineering,
Silpakorn University
Master of Engineering (Material Engineering)
Faculty of Engineering, Rajamangala University of
Technology Thanyaburi (RMUTT)
Doctor of Engineering Program in Energy and
Materials Engineering (International Program),
Faculty of Engineering, Rajamangala University of
Technology Thanyaburi (RMUTT)

Experience Work Printing Section Leader
Fuji name (Thailand) Co., Ltd.
Production Section Leader
Manee Mongkol Import-Export Co., Ltd.
Research Assistant, Department of Materials and
Metallurgical, Engineering Faculty of Engineering,
Rajamangala University of Technology Thanyaburi
(RMUTT) 2012- Present.

Telephone Number 08-4767-1388

Email Address wissanu_c@mail.rmutt.ac.th
